Approaches to Lattice-based cryptography

Low Security Risk Oriented: LWE Approach:

- Advantage: Low Security Risk no lattice structure, relation to worst-case lattices
- **Drawback**: Performance large $\geq + \pi \times + \pi$ matrices, slow computation

High Performance Oriented: PLWE^f Approach

Problem (Search Poly. Learning-with-Errors Search – $PLWE_{a,m,n,\alpha}^{f}$)

Let $R_q = \mathbb{Z}_q[x]/(f(x))$ (e.g. $f(x) = x^n + 1$). Given $\mathbf{A} \to U(R_q^{m \times 1})$ and $\mathbf{y} = \mathbf{A} \cdot \mathbf{s} + \mathbf{e} \mod R_q$ (with \mathbf{e} 'small'), find \mathbf{s} .

- Advantage: Performance succinct matrices, fast poly arithmetic (FFT)
- Drawback: High Security Risk? rely on security of PLWE^f for a fixed f...

イロト イヨト イヨト ・

Risk: $PLWE^{f}/ApproxSVP^{f}$ easy for some f

Problem

ApproxSVP^{*f*} **Problem**: ApproxSVP restricted to ideals in $R = \mathbb{Z}[x]/f(x)$

Weak f's for ApproxSVP^f:

- The case of cyclotomic *f* of prime power index:
 - [CDPR16]: quantum poly. time algorithm to find a short generator of a principal ideal for $2^{O(\sqrt{n})}$ approx. factor
 - [CDW17]: quantum poly. time algorithm to solve ApproxSVP for all ideals for $2^{O(\sqrt{n})}$ approx. factor

• The case of multiquadratic *f*:

- [BBdVLvV17]: quasipoly. time algorithm to find a **short** generator of a principal ideal
- Weak *f*'s for PLWE^{*f*} with 'small' noise:
 - [EHL14,ELOS15,CIV16,Pei16]: poly-time attacks on PLWE^f for weak *f*, when noise is 'small' (vs. canonical embeding lattice geometry)

Risk of fixing f today: future attacks on PLWE^{*f*} for weak f's? Which f?

Titanium: Our MP-LWE-based Approach (Risk-Performance Balance)

Risk-Performance Balance: Titanium MP-LWE-based Approach

- Middle-Product LWE (MP-LWE) [RSSS17]: poly. variant of LWE problem as secure as the hardest PLWE^f for a big family *F* ← of ring polynomials *f*'s
- Lower Security Risk guarantee: hedge risk across class $\mathcal{F} \leftrightarrow f$'s
- **Security-Risk-vs.-Perf. Balance:** Lower security risk guarantee than PLWE^{*f*} schemes, Better performance than LWE schemes

• Our CPA-secure PKE scheme: Titanium-CPA

- Performance: Optimised [RSSS17] PKE
 - Fast FFT-based algorithms for polynomial 'middle-product'
 - Optimised noise/randomness distributions/parameters
 - Constant-time implementation
- Security: Optimised [RSSS17] sec. proof
 - MP-LWE-based: Low security risk from hardest $PLWE^{f}$ over $f \in \mathcal{F}$
 - Used in parameter selection: concrete security lower bound guarantees
 - Conservative choice of parameters

• Our CCA-secure KEM scheme: Titanium-CCA

- Tight CCA conversion (classical ROM) of Titanium-CPA using Fujisaki-Okamoto variant
- Provable resistance to decryption failure attacks

Security Foundations: Middle-Product LWE (MP-LWE) Problem

Middle Product of two polynomials

Let R be a ring, $a \in \mathbb{R}^{< n}[x]$ and $b \in \mathbb{R}^{< n+d-1}[x]$ two polynomials.

Their product is:

$$c_0 + \dots + c_{n-2} x^{n-2}$$
$$+ c_{n-1} x^{n-1} + c_n x^n + \dots + c_{n+d-2} x^{n+d-2}$$

$$+c_{n+d-1}x^{n+d-1}+\cdots+c_{2n+d-3}x^{2n+d-3}\in \mathbb{R}^{<2n+d-2}[x]$$

• Their middle product is:

 $a \odot_d b := c_{n-1} + c_n \cdot x + \cdots + c_{n+d-2} \cdot x^{d-1} \in \mathbb{R}^{\leq d}[x]$

Decision $\mathsf{PLWE}_{q,\alpha,\chi}^{f}$ Problem

Let $s \to (U(\mathbb{Z}_q[x]/f))$, $a_i \to U(\mathbb{Z}_q[x]/f)$ and $e_i \to \chi^n$ 'small'. Distinguish between $(a_i, b_i = a_i \cdot \cdot \cdot \cdot + e_i)_i$ and $(a_i, b_i \to U(\mathbb{Z}_q[x]/f))_i$

Decision MP-LWEⁿ_{q,α,χ,d} Problem

Let $s \to (U(\mathbb{Z}_q[x]^{\leq n+d-1}))$, $a_i \to U(\mathbb{Z}_q^{\leq n}[x])$ and $e_i \to \chi^d$ 'small'. Distinguish between $(a_i, b_i = a \odot_d s + e)_i$ and $(a_i, b_i \to U(\mathbb{Z}_q^{\leq d}[x]))_i$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

Hardness of MP-LWE

Let $n \geq 4$, $q \geq 2$, and $\alpha \in (0, 1)$, χ balanced.

Theorem (Hardness of MP-LWE^{*n*}_{*q*, α,χ,d'} (RSSS17 + SSZ17))

 $\mathsf{PLWE}_{q,\alpha,\chi}^{f}$ reduces to $\mathsf{MP-LWE}_{q,\alpha,\chi,d'}^{n}$ for **any** monic $f \in \mathbb{Z}[x]$ in family $\mathcal{F}(n,m',d')$ s.t.

•
$$f(x) = x^m + \sum_{i \not\in \ell(m)} f_i x^i$$

•
$$\ell(m) = \min(m/2 + 1, m + 1 - d')$$

•
$$d' \leq m' \leq m \leq n$$

•
$$f_0 \in \{-1, 1\}.$$

- Tight Reduction w.r.t. running-time, advantage, and preserves noise distribution
- Improves on noise amplifying reduction of [RSSS17]
- For Titanium, we use $\chi = \mathsf{BinDiff}(\eta)$, diff. of binomials ($pprox \mathsf{Gaussian}$)

Polynomial Family $\mathcal{F}_1 = \mathcal{F}(n, m', d')$ of f for Titanium security foundation

$$\begin{split} f(x) &= x^m + \sum_{i \leq \ell(m)} f_i x^i, \\ \text{Family degree range } m_{min} &= m' \leq m \leq m_{max} = n \\ \text{Deg. of largest non-leading monomial } \ell(m') &= \text{gap}_2 = m_{min} - d' \end{split}$$

Parameters of \mathcal{F}_1 **for** Titanium-CCA:

Titanium Algorithms (Simplified Versions) and Par. Sets

Titanium-CPA Key Gen. Algorithm

Algorithm 1 : Titanium-CPA.KeyGen

Input: 1^{λ} .

Output: pk and sk.

1: function KeyGen (1^{λ}) 2: Let $s \rightarrow U(\mathbb{Z}_q^{\leq n+d+k-1}[x])$. 3: Let $(a_1, \ldots, a_t) \rightarrow U(\mathbb{Z}_q^{\leq n}[x])^t$. 4: Let $(e_1, \ldots, e_t) \rightarrow \chi_e \in (\mathbb{Z}_q^{\leq d+k}[x])^t$. 5: for $i \leq \notin$ -do 6: Let $b_i = a_i \odot_{d+k} s + e_i \in \mathbb{Z}_q^{\leq d+k}[x]$. 7: end for 8: Let $p_k = ((a_1, \ldots, a_k)) (b_k = b_k)$ and

8: Let
$$\mathsf{pk} = ((a_1, \ldots, a_t), (b_1, \ldots, b_t))$$
 and $\mathsf{sk} = s$.

9: end function

Omitted from above version (using XOF = SHA-3 KMAC256 PRF/"RO"):

- Pseudorandom gen. of s and (e_1, \ldots, e_t) from seedsk stored in sk
- "Pseudorandom" gen. of (a_1, \ldots, a_t) from seedpk stored in pk
- *a_i* sampled in reversed coeff. format (for efficient MP algorithm)

Ron Steinfeld (Monash University)

Titanium-CPA Encryption. Algorithm

Algorithm 2 : Titanium-CPA.Encrypt

Input:
$$pk = ((a_1, ..., a_t), (b_1, ..., b_t))$$
 and $m \in \mathbb{Z}_p^{.
Output: $ct = (c'_1, c'_2)$.$

1: **function** Encrypt(pk, m)

2: Let
$$(r_1,\ldots,r_t) \rightarrow \chi_r \in (\mathbb{Z}_q^{\leq k+1}[x])^t$$
.

3: Let
$$c'_1 = \sum_{i=1}^t r_i \cdot a_i$$

4: Let
$$c'_2 = \sum_{i=1}^t r_i \odot_d b_i + \lfloor q/p \rfloor \cdot m \in \mathbb{Z}_q^{\leq d}[x]$$
.
5: end function

Omitted from above version (using XOF = SHA-3 KMAC256 PRF/RO):

- Pseudorandom generation of (r_1, \ldots, r_t) from seedr
- "Pseudorandom" gen. of (a_1, \ldots, a_t) from seedpk stored in pk
- a_i sampled in reversed coeff. format, $r_i \odot_d b_i$ replaced by $\operatorname{Rev}(r_i) \odot_d b_i$ (for efficient MP algorithm)

Ron Steinfeld (Monash University)

Algorithm 3 : Titanium-CPA.Decrypt

Input: sk = s and $ct = (c'_1, c'_2)$. **Output:** m'.

1: function Decrypt(sk, ct)

2: Let
$$c' = c'_2 - c'_1 \odot_d s \in \mathbb{Z}_q^{< d}[x].$$

3: Let
$$m' = \operatorname{Round}(\lfloor q/p \rfloor, c') \in \mathbb{Z}_p^{\leq d}[x].$$

4: end function

Omitted from above version (using XOF = SHA-3 KMAC256 PRF/RO):

- Pseudorandom gen. of *s* from seedsk stored in sk
- $c'_1 \odot_{_d} s$ replaced by $\operatorname{Rev}(c'_1) \odot_{_d} s$ (for efficient MP algorithm)

- Generic Fujisaki-Okamoto CPA to CCA transformation applied to Titanium-CPA [HHK07]
 - Decryption returns pseudorandom value if ciphertext validity check fails
- Uses two hash functions G,H = SHA-3 based SHAKE256 "random oracles"

$$c' \quad = \quad c'_2 - c'_1 \odot_d s$$

$$c' = c'_2 - c'_1 \odot_d s$$

= $\sum_{i=1}^t r_i \odot_d b_i + \lfloor q/p \rfloor \cdot m - \sum_{i=1}^t (i \cdot a_i) (\odot_d s)$

Image: Image:

→ < ∃ →</p>

27/03/2018 18 / 47

$$c' = c'_{2} - c'_{1} \odot_{d} s$$

$$= \sum_{i=1}^{t} r_{i} \odot_{d} b_{i} + \lfloor q/p \rfloor \cdot m - \sum_{i=1}^{t} (i \cdot a_{i}) (\bigcirc_{d} s$$

$$= \sum_{i=1}^{t} r_{i} \odot_{d} (a_{i} \odot_{d+k} s + e_{i}) + \lfloor q/p \rfloor \cdot m - \sum_{i=1}^{t} (r_{i} \cdot a_{i}) \odot_{d} s$$

► < ∃ ►</p>

$$c' = c'_{2} - c'_{1} \odot_{d} s$$

$$= \sum_{i=1}^{t} r_{i} \odot_{d} b_{i} + \lfloor q/p \rfloor \cdot m - \sum_{i=1}^{t} \left(i \cdot a_{i} \right) \left(\bigcirc_{d} s \right)$$

$$= \sum_{i=1}^{t} r_{i} \odot_{d} (a_{i} \odot_{d+k} s + e_{i}) + \lfloor q/p \rfloor \cdot m - \sum_{i=1}^{t} \left(r_{i} \cdot a_{i} \right) \odot_{d} s$$

$$= \lfloor q/p \rfloor \cdot m + \sum_{i=1}^{t} \left(i \odot_{d} e_{i} \in \mathbb{Z}_{q}^{d}[x] \approx \lfloor q/p \rfloor \cdot m,$$

using 'associative' property of middle-product:

$$r_i \odot_d (a_i \odot_{d+k} s) = (r_i \cdot a_i) \odot_d s$$

Compute tight upper bound on decryption error prob. p_e (Hoeffding)

- We specify total of 6 different parameters sets Toy64, Lite96, Std128, Med160, Hi192, Super256
 - $\bullet~$ last digits = equivalent symmetric key search security level
- Achieve NIST security goals at high quantum key search security goals (MAXDEPTHMD = 2^{40})
 - Std128 NIST level 1 (AES-128): goal $\lambda_C = 143$, $\lambda_Q = 130$
 - Hi192 NIST level 3 (AES-192): goal $\lambda_C = 207$, $\lambda_Q = 193$
 - Super256 NIST level 5 (AES-256): $\lambda_C = 272$, $\lambda_Q = 258$

Design Rationale

• Choice of Error distributions:

- **1** Secret key: Uniform distrib. coeffs over \mathbb{Z}_q
 - sample directly in the NTT domain from seedsk (save NTT)
- **2** Uniform distrib. over $[-2^b, 2^b]$ for encryption randomness coeff.
 - Uniform shape: max. min-entropy (LHL) for given variance (dec. error probability)
 - Size of *b*: optimize to reduce pk+ciph size
 - Power of 2: efficient sampling
 - Fine tweak: two int. values of b for two subsets of r_i coeffs.
- S 'Binomial Difference' distribution for errors = Bin(4, 1/2) Bin(4, 1/2)
 - std. dev. of error coeff. = $\sqrt{2}$, fast constant-time sampling
 - $\bullet~\approx$ Gaussian shape as in worst-case hardness proofs

Design Rationale

• Choice of Error distributions:

 - std. dev. of error coeff. = $\sqrt{2}$, fast constant-time sampling
 - $\bullet~\approx$ Gaussian shape as in worst-case hardness proofs

• Decryption error probability p_e :

- A moderate goal $p_e = 2^{-30}$ for Titanium-CPA, and
- Set to a cryptographically negligible value for Titanium-CCA (provably avoid decryption failure attacks)

Optimized Implementation

• Fast Middle Product Algorithm and Optimisations:

- Middle product NTT-based algorithm,
 - 3 NTT dims needed: $d_1 \ge d + k, d_2 \ge n + k, d_3 \ge n + d + k 1$
 - Choice of NTT dims: small multiples of 256
 - Core NTT = radix 2 algorithm in dim. 256
 - Choice of parameters k, n: close to multiples of 256 (min. pad)
 - Choice of q: 'NTT-friendly' prime wrt d₁, d₂, d₃.
 - Partial MP-NTT: exploit MP truncation, input padding
 - Fast mod q reduction (Barret and Mongomery),
- Optimised Titanium-CPA and Titanium-CCA Algorithms:
 - Precompute pub-key NTT in keygen. (save NTT from enc and CCA dec)
 - Sample secret key directly in NTT domain (save NTT)
- Onstant-time implementation:

Intel AVX2 instruction set

Titanium Security Analysis

Main security analysis approach:

- **Concrete security proof** from hardest $PLWE^{f}$ over f in family \mathcal{F} :
 - Part 1: Security of Titanium-CPA/Titanium-CCA from hardness of MP-LWE
 - Part 2: MP-LWE hardness from PLWE^f hardness over many f's
 - Already discussed in 'security foundations'
- Use proof bounds to select parameters: low bound for security of Titanium-CPA/Titanium-CCA, assuming
 - best known dual BKZ attack on $PLWE^{f}$ (any f in family \mathcal{F})
 - conservative 'Core SVP' security estimate for dual BKZ attack [ADPS16]
 - We followed **more conservative/higher safety margins** (bigger than some other lattice-based proposals)

Theorem (IND-CPA of Titanium-CPA from MP-LWE)

Assume q is prime and Leftover Hash Lemma (LHL) condition holds:

$$t \cdot \langle k+1 \rangle \cdot \langle b_{\mathsf{LHL}} \ge 2 \cdot \langle \log(\Delta_{\mathsf{LHL}}^{-1}) - 1 \rangle + (n+d+k) \cdot \langle \log q.$$
(1)

Then, any IND-CPA attack against Titanium-CPA with run-time T and advantage ε in the (classical) Random Oracle Model for XOF (Q queries), implies an IND-CPA attack against MP-LWEⁿ_{q, $\alpha, \chi, d'=d+k$} with run-time $T' \approx \mathcal{F}$, and distinguishing advantage

$$\varepsilon' \ge \varepsilon/2 - 3 \cdot \varepsilon/2^{256} - \Delta_{LHL}.$$
⁽²⁾

- b_{LHL} = bit length of encryption random polynomials r_i
- XOF = hash function used to derive randomness from short seeds
- Δ_{LHL} chosen as $O(2^{-\lambda})$ for security parameter λ

Proof idea

Recall Titanium-CPA ciphertext form

$$c_1 = \sum_{1 \leq i \leq t} r_i \cdot a_i$$
 and $c_2 = \sum_{1 \leq i \leq t} (r_i \odot_d b_i + m \cdot \lfloor q/2 \rfloor)$

using random r_i 's with 'small' coefficients each with entropy b_{LHL} .

Security argument ([RSSS17], variant of 'primal Regev'):

- Replace in key gen. $(a_i \rightarrow U(\mathbb{Z}_q^{< n}[x]), b_i = a_i \odot_{d+k} s + e_i)$ with uniformly pairs $(a_i \rightarrow U(\mathbb{Z}_q^{< n}[x]), b_i \rightarrow U(\mathbb{Z}_q^{< d+k}[x]))$.
 - MP-LWE $_{q,\alpha,\chi,d'=d+k}^n$ hardness implies attacker's view stays comp. indistinguishable
- Now, in challenge c_2 , $\sum_{1 \le i \le t} r_i \odot_d b_i$ is stat. indistinguishable from uniform on $\mathbb{Z}_q^{\le d}[x]$ (given pub key and c_1), stat. masks message m
 - Implied by 'generalized' Leftover Hash Lemma (LHL) if *q* prime and min-entropy of *r_i*'s sufficiently exceeds max-entropy of ciphertext space
 - c_1 = 'auxilliary information' on r_i 's, not uniform (no security impact)

Theorem (IND-CCA of Titanium-CCA from MP-LWE)

Assume q is prime, LHL condition holds and Titanium-CPA is p_e -correct. Then, any IND-CCA attack against Titanium-CCA with run-time T and advantage ε with at most Q_{XOF} , Q_G , Q_H queries in the (classical) Random Oracle Model for XOF, G and H respectively, implies an attack against MP-LWE $^n_{q,\alpha,\chi,d'=d+k}$ with run-time $T' \approx \langle T, \rangle$ and distinguishing advantage

$$\varepsilon' \geq \frac{1}{6} \cdot \left(\left(-Q_{\mathsf{G}} \cdot \varphi_{\mathsf{e}} - \Delta_{\mathsf{LHL}} - \frac{10 \cdot Q_{\mathsf{XOF}} + 2 \cdot Q_{\mathsf{G}} + Q_{\mathsf{H}} + 1}{2^{256}} \right) \right) (3)$$

- Tight proof by combining Titanium-CPA proof with tight Fujisako-Okamoto transform proof [HHK17]
- p_e set to $O(2^{-\lambda})$ provably avoid decryption fail attacks
- Classical ROM could be replaced by quantum ROM [HHK17] (but with non-tight security reduction)

Ron Steinfeld (Monash University)

27/03/2018 28 / 47

How we set the Titanium-CPA/Titanium-CCA parameters

Def. of quantum (classical) security levels λ_Q (λ_C): For any attack with time $T_Q \leq \mathcal{Q}^{\lambda_Q}$ ($T_C \leq \mathcal{Q}^{\lambda_C}$) and advantage ε_Q (ε_C), we have $T_Q/\varepsilon_Q \geq \mathcal{Q}^{\lambda_Q}$ ($T_C/\varepsilon_C \geq \mathcal{Q}^{\lambda_C}$).

- Time = no. of elem. quantum (classical) gates
- RO query cost = $T_{QRO} \approx Q^{19}$ qu. ($T_{RO} \approx Q^{19}$ cl.) gates
- RO query quantum depth = $D_{QRO} = 2^{13}$ qu. gates

Main parameter selection goal: Set parameters (using security proof) to get **proven** 2^{λ_c} classical security level for Titanium-CPA/Titanium-CCA, assuming:

- Hardest PLWE^f security level $(f \in \mathcal{F}) = \mathsf{sec.}$ level of best known PLWE^f attack (dual lattice attack)
- $\bullet\,$ Classical random oracle model for symmetric key-based functions H,G,XOF
- Conservative 'core SVP' methodology [ADPS16] to estimate dual lattice attack complexity level

Ron Steinfeld (Monash University)

How we set the Titanium-CPA/Titanium-CCA parameters

Quantum security estimate approach:

- **Problem:** Existing **quantum** random oracle model security proofs for Titanium-CPA/Titanium-CCA are not tight
- **Approach:** Modify classical bounds to account for Grover search bounds:
 - Replace classical 'bad event prob.' terms $Q \cdot \hat{\phi_{\tau}}$ in classical proof:

$$p_C \leq Q \cdot \Phi$$

• by quantum 'Grover-search' bounds with Q/Q_D parallel Grover search circuits of depth Q_D queries :

$$p_Q \leq \ll \cdot (Q/Q_D) \cdot Q_D^2 \cdot \ll$$

- Max Quantum Depth (MD) constraint: $MD = 2^{40}, 2^{64}, 2^{96}$ gates: we satisfy security goals at all these MD values.
- Maximum number of queries in quantum Grover search $Q_D = \min(\text{MD}, 2^{\lambda_Q})/D_{QRO}$

Parameter Setting: Conservative assumptions

Our conservative parameter setting assumptions:

- Include security proof reduction costs in parameter selection
- Extra safety margins for future cryptanalytic progress:
 - 10% safety margin on quantum bit security level
- Use minimum f degree m_{min} in \mathcal{F} for PLWE^f hardness estimates
- 'Core SVP' approach for PLWE^f dual attack BKZ cost leave room for future cryptanalytic progress:
 - lower bound gate complexity of BKZ-b by $T = 2^{0.292 \cdot b}$ (resp. $2^{0.265 \cdot b}$)
 - don't rely on additional costs related to
 - no. of SVP calls of BKZ, memory access costs, Grover iteration costs
 - remark: some proposals assume costs: harder to compare proposals.
 - Q: Could NIST recommend a standard cost measure for BKZ?
 - assume each sieve SVP call provides up T (not only M) short vectors
 - unlimited quantum circuit depth for SVP sieve
- Don't rely on MP-LWE being harder than PLWE^f
 - $\bullet\,$ although best known attack on MP-LWE is significantly harder

Best known attacks on Titanium-CPA/Titanium-CCA: is MP-LWE harder than PLWE^f?

Our proof shows MP-LWE^{*n*}_{*q*, α,χ,d'} is **at least** as hard as PLWE^{*f*}_{*q*, α,χ}. Is it actually **harder** for small no. of MP-LWE samples *t*?

Best known attack on MP-LWE^{*n*}_{*q*, α,χ,d'} has higher complexity than PLWE^{*f*}_{*q*, $\alpha,\chi}$:}

- Generic LWE attack on MP-LWEⁿ_{q,α,χ,d'} uses secret in dimension n + d', versus $\leq n$ for PLWE^f_{$q,\alpha,\chi}$ </sub>
- We give an MPLWE-optimised LWE attack to reduce secret dimension down to $n + m/t \approx m$ for *m* LWE samples:
 - Idea: Exploit the zeros in the Toeplitz matrix for a_i 's: Keep only m/t top rows of each Toeplitz matrix
 - Still leaves a hardness gap of $q^{1/t}$ in approx.-SVP factor to best known attack on $\mathsf{PLWE}_{q,\alpha,\chi}^f$ with f in dimension n

Best known attacks on Titanium-CPA/Titanium-CCA: MP-LWE Complexity estimates

'Core-SVP' Complexity of MPLWE-optimised primal embedding LWE attack on MP-LWEⁿ_{q,\alpha,\chi,d'} ($\lambda_{C,\text{emb},2}/\lambda_{C,\text{emb},2}$), compared to PLWE^f_{q,\alpha,\chi} with f in dimension n ($\lambda_{C,\text{PLWE},m_{\text{max}}}/\lambda_{C,\text{PLWE},m_{\text{max}}}$) and scheme goals (λ_{C}/λ_{Q})

Par. Set	$\lambda_{C,\mathrm{emb},2}$	$\underset{\lambda_{\mathcal{C},PLWE,m_{max}}{PLWE,m_{max}}$	λ _C	$\lambda_{Q,{\rm emb},2}$	Quantum $\lambda_{Q, PLWE, m_{max}}$	λ _Q

Titanium-CCA-Std128-AES: Titanium-CCA with AES PRG (new implementation, not in NIST sub.)

Ron Steinfeld (Monash University)

27/03/2018 42 / 47

Implementation Updates after NIST submission

Ron Steinfeld (Monash University)

Titanium: Post-Quantum PKC

27/03/2018 43 / 47

- NIST implementation may not be constant time depending on C compiler imp of % mod reduction
 - Rewrote mod reduction to avoid % compiler independent constant-time
- Improved efficiency of NTT implementation
 - by merging intermediate levels of radix-2 NTT (mod red at end only)
- Added OpenQuantum integration for Titanium
- New AES-based PRG Titanium variant Titanium AES (not in NIST submission)
 - Faster symmetric-key XOF for *a_i*, *sk* gen. using Intel AES-NI instructions
- Updated Implementation benchmarks
