Foreword

20 The Federal Information Processing Standards Publication Series of the National Institute of Standards and
21 Technology is the official series of publications relating to standards and guidelines developed under 15
22 U.S.C. 278g-3, and issued by the Secretary of Commerce under 40 U.S.C. 11331.

23 Comments concerning this Federal Information Processing Standard publication are welcomed and should
24 be submitted using the contact information in the “Inquiries and comments” clause of the announcement
25 section.

Abstract

28 In 2000, NIST announced the selection of the Rijndael block cipher family as the winner of the
29 Advanced Encryption Standard (AES) competition. Three members of the Rijndael family are
30 specified in this Standard: AES-128, AES-192, and AES-256.

31 **Keywords:** AES; block cipher; confidentiality; cryptography; encryption; Rijndael.

32 **Federal Information**
33 **Processing Standards Publication 197**

34 **Published: November 26, 2001**

35 Updated: December 19, 2022

36 **Announcing the**
37 **ADVANCED ENCRYPTION STANDARD (AES)**

38 Federal Information Processing Standards Publications (FIPS) are developed by NIST under 15
39 U.S.C. 278g-3, and issued by the Secretary of Commerce under 40 U.S.C. 11331.

- 40 1. **Name of Standard.** Advanced Encryption Standard (AES) (FIPS 197).
41 2. **Category of Standard.** Computer Security Standard, Cryptography.
42 3. **Explanation.** The Advanced Encryption Standard (AES) specifies a FIPS-approved cryp-
43 tographic algorithm that can be used to protect electronic data. The AES algorithm is a
44 symmetric block cipher that can encrypt (encipher) and decrypt (decipher) digital information.
45 The AES algorithm is capable of using cryptographic keys of 128, 192, and 256 bits to encrypt
46 and decrypt data in blocks of 128 bits.
47 4. **Approving Authority.** Secretary of Commerce.
48 5. **Maintenance Agency.** Department of Commerce, National Institute of Standards and Tech-
49 nology, Information Technology Laboratory (ITL).
50 6. **Applicability.** Federal Information Processing Standards apply to information systems used
51 or operated by federal agencies or by a contractor of an agency or other organization on behalf
52 of an agency. They do not apply to national security systems as defined in 44 U.S.C. 3552.

53 This Standard may be used by federal agencies to protect information when they have deter-
54 mined that encryption is appropriate, in accordance with applicable Office of Management
55 and Budget and agency policies. Federal agencies may also use alternative methods that NIST
56 has indicated are appropriate for this purpose.

57 This Standard may be adopted and used by non-federal government organizations.

- 58 7. **Specifications.** Federal Information Processing Standard (FIPS) 197, Advanced Encryption
59 Standard (AES) (affixed).
60 8. **Implementations.** The algorithm specified in this Standard may be implemented in software,
61 firmware, hardware, or any combination thereof. The specific implementation may depend
62 on several factors such as the application, the environment, the technology used, etc. The
63 algorithm shall be used in conjunction with a FIPS-approved or NIST- recommended mode
64 of operation. Object Identifiers (OIDs) and any associated parameters for AES used in

65 these modes are available at the Computer Security Objects Register (CSOR), located at
66 <https://csrc.nist.gov/projects/csor>.

67 NIST has developed a validation program to test implementations for conformance to the
68 algorithms in this Standard. Information about the validation program is available at <https://nist.gov/cmvp>. Examples for each key size are available at <https://csrc.nist.gov/projects/aes>.
69

70 **9. Implementation Schedule.** This Standard became effective on May 26, 2002.

71 **10. Patents.** Implementations of the algorithm specified in this Standard may be covered by U.S.
72 and foreign patents.

73 **11. Export Control.** Certain cryptographic devices and technical data regarding them are subject
74 to federal export controls. Exports of cryptographic modules implementing this Standard and
75 technical data regarding them must comply with all federal laws and regulations and must
76 be licensed by the Bureau of Industry and Security of the U.S. Department of Commerce.
77 Information about export regulations is available at: <https://www.bis.doc.gov>.

78 **12. Qualifications.** NIST will continue to follow developments in the analysis of the AES
79 algorithm. As with its other cryptographic algorithm standards, NIST will formally reevaluate
80 this Standard every five years.

81 Both this Standard and possible threats reducing the security provided through the use of this
82 Standard will undergo review by NIST as appropriate, taking into account newly available
83 analysis and technology. In addition, the awareness of any breakthrough in technology or
84 any mathematical weakness of the algorithm will cause NIST to reevaluate this Standard and
85 provide necessary revisions.

86 **13. Where to obtain copies.** This publication is available by accessing [https://csrc.nist.gov/](https://csrc.nist.gov/publications)
87 [publications](https://csrc.nist.gov/publications). Other computer security publications are available at the same website.

88 **14. Inquiries and comments.** Inquiries and comments about this FIPS may be submitted to
89 cryptopubreviewboard@nist.gov. The public comment period for this draft FIPS is open
90 through February 13, 2023.

91 **15. How to Cite this Publication.** NIST has assigned **NIST FIPS 197-upd1 ipd** (initial public
92 draft) as the publication identifier for this FIPS, per the [NIST Technical Series Publication](#)
93 [Identifier Syntax](#). NIST recommends that it be cited as follows:

94 National Institute of Standards and Technology (2001) Advanced Encryption
95 Standard (AES). (Department of Commerce, Washington, D.C.), Federal Informa-
96 tion Processing Standards Publication (FIPS) NIST FIPS 197-upd1 ipd, updated
97 December 19, 2022. <https://doi.org/10.6028/NIST.FIPS.197-upd1.ipd>

1. Introduction

A *block* is a sequence of bits of a given, fixed length. A *block cipher* is a family of permutations of blocks that is parameterized by a sequence of bits called the *key*.

In 1997, NIST initiated the Advanced Encryption Standard (AES) development effort [1] and called for the public to submit candidate algorithms for block ciphers. Block ciphers are the foundation for many cryptographic services, especially those that provide assurance of the confidentiality of data. In 2000, NIST announced the selection of Rijndael [2, 3] for the AES.

This Standard specifies three instantiations of Rijndael: AES-128, AES-192, and AES-256, where the suffix indicates the bit length of the key. The block size, i.e., the length of the data inputs and outputs, is 128 bits in each case. Rijndael supports additional block sizes and key lengths that are not adopted in this Standard.

This Standard is organized as follows:

- Section 2 defines the terms, acronyms, algorithm parameters, symbols, and functions in this Standard.
- Section 3 describes the notation and conventions for the ordering and indexing of bits, bytes, and words.
- Section 4 explains some mathematical components of the AES specifications: finite field arithmetic and multiplication by a fixed matrix of finite field elements.
- Section 5 specifies AES-128, AES-192, and AES-256.
- Section 6 provides implementation guidelines on key length requirements, keying restrictions, parameter extensions, and implementation suggestions regarding various platforms.
- Appendix A gives examples of the key expansion routines for AES-128, AES-192, and AES-256.
- Appendix B gives a step-by-step example of an invocation of AES-128.
- Appendix C gives a reference to the NIST web site for extensive example vectors for AES-128, AES-192, and AES-256.
- Appendix D summarizes the updates to the original version of this publication.

2. Definitions

2.1 Terms and Acronyms

The following definitions are used in this Standard:

199	AES	Advanced Encryption Standard.
200	Affine transformation	A transformation consisting of multiplication by a matrix, followed by the addition of a vector.
201	Array	A fixed-size data structure that stores a collection of elements, where each element is identified by its integer index or indices.
202	Bit	A binary digit: 0 or 1.
203	Block	A sequence of bits of a given, fixed length. In this Standard, blocks consist of 128 bits, sometimes represented as arrays of bytes or words.
204	Block cipher	A family of permutations of blocks that is parameterized by the key.
205	Byte	A sequence of eight bits.
206	Equivalent inverse cipher	An alternative specification of the Inverse of CIPHER() with a structure similar to that of CIPHER() and with a modified key schedule as input.
207	Key	The parameter of a block cipher that determines the selection of a permutation from the block cipher family.
208	Key schedule	The sequence of round keys that are generated from the key by KEYEXPANSION().
209	Rijndael	The block cipher that NIST selected as the winner of the AES competition.
210	Round	A sequence of transformations of the state that is iterated Nr times in the specifications of CIPHER(), INVCIPHER(), and EQINVCIPHER(). The sequence consists of four transformations, except for one iteration, in which one of the transformations is omitted.
211	Round key	One of the $Nr + 1$ arrays of four words that are derived from the block cipher key using the key expansion routine; each round key is an input to an instance of ADDROUNDKEY() in the AES block cipher.
212	State	Intermediate result of the AES block cipher that is represented as a two-dimensional array of bytes with four rows and Nb columns.
213	S-box	A non-linear substitution table used in SUBBYTES() and KEYEXPANSION() to perform a one-to-one substitution of a byte value.
214	Word	A group of 32 bits that is treated either as a single entity or as an array of 4 bytes.

215 2.2 List of Functions

216 The following functions are specified in this Standard:

217	ADDRoundKey()	The transformation of the state in which a round key is combined with the state.
218	AES-128()	The block cipher specified in this Standard with 128-bit keys.
219	AES-192()	The block cipher specified in this Standard with 192-bit keys.
220	AES-256()	The block cipher specified in this Standard with 256-bit keys.
221	CIPHER()	The transformation of blocks that underlies AES-128, AES-192, and AES-256; the key schedule and the number of rounds are parameters of the transformation.
222	EQINVCIPHER()	The inverse of CIPHER() in which d_w replaces w as the key schedule parameter.
223	INVCIPHER()	The inverse of CIPHER().
224	INVMIXCOLUMNS()	The inverse of MIXCOLUMNS().
225	INVSBOX()	The inverse of SBOX().
226	INVSHIFTRROWS()	The inverse of SHIFTRROWS().
227	INVSUBBYTES()	The inverse of SUBBYTES().
228	KEYEXPANSION()	The routine that generates the round keys from the key.
229	KEYEXPANSIONEIC()	The routine that generates the modified round keys for the equivalent inverse cipher.
230	MIXCOLUMNS()	The transformation of the state that takes all of the columns of the state and mixes their data (independently of one another) to produce new columns.
231	ROTWORD()	The transformation of words in which the four bytes of the word are permuted cyclically.
232	SBOX()	The transformation of bytes defined by the S-box.
233	SHIFTRROWS()	The transformation of the state in which the last three rows are cyclically shifted by different offsets.
234	SUBBYTES()	The transformation of the state that applies the S-box independently to each byte of the state.
235	SUBWORD()	The transformation of words in which the S-box is applied to each of the four bytes of the word.
236	XTIMES()	The transformation of bytes in which the polynomial representation of the input byte is multiplied by x , modulo $m(x)$, to produce the polynomial representation of the output byte.

237 2.3 Algorithm Parameters and Symbols

238	b^{-1}	The multiplicative inverse of the element b in $\text{GF}(2^8)$.
239	\tilde{b}	The input to the affine transformation in the AES S-box.
240	dw	Word array for the key schedule that is input to the equivalent inverse cipher.
241	$\text{GF}(2)$	Finite field with 2 elements.
242	$\text{GF}(2^8)$	Finite field with 256 elements.
243	in	The data input to $\text{CIPHER}()$ or $\text{INVCIPHER}()$, represented as an array of 16 bytes indexed from 0 to 15.
244	$m(x)$	The modulus specified in this standard for the polynomial representation of bytes as elements of $\text{GF}(2^8)$.
245	key	The array of Nk words that comprise the key for AES-128, AES-192, or AES-256.
246	Nb	The number of columns comprising the state, where each column is a 32-bit word. For this Standard, $Nb = 4$.
247	Nk	The number of 32-bit words comprising the key. Nk is assigned to 4, 6, and 8 for AES-128, AES-192, and AES-256, respectively. (see Section 6.3).
248	Nr	The number of rounds. Nr is assigned to 10, 12, and 14 for AES-128, AES-192, and AES-256, respectively.
249	out	The data output of $\text{CIPHER}()$ or $\text{INVCIPHER}()$, represented as an array of 16 bytes indexed from 0 to 15.
250	$Rcon$	Word array for the round constant.
251	$state$	The state, represented as a two-dimensional array of 16 bytes, with rows and columns indexed from 0 to 3.
252	$u[i]$	For a one-dimensional array u of words or bytes, the element in the array that is indexed by a non-negative integer i .
253	$u[i..i+3]$	For an array u of words, the sequence $u[i], u[i+1], u[i+2], u[i+3]$.
254	w	Word array for the key schedule.
255	\oplus	Either the exclusive-OR operation on bits, or the bitwise exclusive-OR operation on bytes or words.
256	\bullet	Multiplication in $\text{GF}(2^8)$.
257	$*$	Integer multiplication.
258	\leftarrow	Assignment of a variable in pseudocode.
259	$\{\}$	Delimiters for a byte in hexadecimal or binary notation.

3. Notation and Conventions

3.1 Inputs and Outputs

A *bit* is a binary digit, i.e., 0 or 1. A *block* is a sequence of 128 bits; the data input and output for the AES block ciphers are blocks. Another input to the AES block ciphers, called the *key*, is a bit sequence that is typically established beforehand and maintained across many invocations of the block cipher. The lengths of the keys for AES-128, AES-192, and AES-256 are 128 bits, 192 bits, and 256 bits, respectively.

3.2 Bytes

The basic processing unit in the AES algorithms is the *byte* — a sequence of eight bits.

A byte value is denoted by the concatenation of the eight bits between braces, e.g., {10100011}. When the bits of a byte are denoted by an indexed variable, the convention in this Standard is for the indices to decrease from left to right, i.e., { $b_7 b_6 b_5 b_4 b_3 b_2 b_1 b_0$ }.

It is also convenient to denote byte values using hexadecimal notation. The sixteen hexadecimal characters represent sequences of four bits, as listed in Table 1. A byte is represented by an ordered pair of hexadecimal characters, where the left character in the pair represents the four left-most bits, i.e., b_7, b_6, b_5, b_4 , and the right character in the pair represents the four right-most bits, i.e., b_3, b_2, b_1, b_0 . For example, the hexadecimal form of the byte {10100011} is {a3}.

Table 1. Hexadecimal representation of 4-bit sequences.

Sequence	0000	0001	0010	0011	0100	0101	0110	0111
Character	0	1	2	3	4	5	6	7
Sequence	1000	1001	1010	1011	1100	1101	1110	1111
Character	8	9	a	b	c	d	e	f

3.3 Indexing of Byte Sequences

In order to unambiguously represent the data and key inputs as sequences of bytes, the following indexing convention is adopted in this Standard: given a sequence of $8k$ bits

$$r_0 r_1 r_2 \dots r_{(8k-3)} r_{(8k-2)} r_{(8k-1)}, \quad (3.1)$$

(for some positive integer k), the bytes a_j , for $0 \leq j \leq k - 1$, are defined as follows:

$$a_j = \{r_{8j} r_{(8j+1)} \dots r_{(8j+7)}\}. \quad (3.2)$$

Thus, for example, the data block

$$r_0 r_1 r_2 \dots r_{125} r_{126} r_{127} \quad (3.3)$$

282 is represented by the byte sequence

$$a_0 a_1 a_2 \dots a_{13} a_{14} a_{15} \quad (3.4)$$

where

$$\begin{aligned} a_0 &= \{r_0 r_1 \dots r_7\}; \\ a_1 &= \{r_8 r_9 \dots r_{15}\}; \\ &\vdots \\ a_{15} &= \{r_{120} r_{121} \dots r_{127}\}. \end{aligned} \quad (3.5)$$

283 As described in Section 3.2 the bits within any individual byte are indexed in decreasing order
284 from left to right. This ordering is more natural for the finite field arithmetic on bytes that is
285 described in Section 4. The two types of bit indices for byte sequences are illustrated in Table 2.

Table 2. Indices for bytes and bits.

Bit index in sequence	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	...
Byte index	0								1								...
Bit index in byte	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	...

286 3.4 The State

287 Internally, the algorithms for the AES block ciphers are performed on a two-dimensional (four-
288 by-four) array of bytes called the *state*. In the state array, denoted by s , each individual byte has
289 two indices: a row index r in the range $0 \leq r < 4$ and a column index c in the range $0 \leq c < 4$.
290 An individual byte of the state is denoted by either $s_{r,c}$ or $s[r,c]$.

291 In the specifications for the AES block cipher algorithms in Section 5, the first step is to copy the
292 input array of bytes, in , to the state array s as follows:

$$s[r,c] = in[r+4c] \quad \text{for } 0 \leq r < 4 \text{ and } 0 \leq c < 4. \quad (3.6)$$

293 A sequence of transformations is then applied to the state array, after which its final value is
294 copied to the output array of bytes $out_0, out_1, \dots, out_{15}$ as follows:

$$out[r+4c] = s[r,c] \quad \text{for } 0 \leq r < 4 \text{ and } 0 \leq c < 4. \quad (3.7)$$

295 The correspondence between the indices of the input and output with the indices of the state array
296 is illustrated in Fig. 1.

Figure 1. State array input and output.

297 3.5 Arrays of Words

298 A *word* is a sequence of four bytes; a block consists of four words. The four columns of state
 299 array s are interpreted as an array v of four words as follows, in the notation of Fig. 1:

$$v_0 = \begin{pmatrix} s_{0,0} \\ s_{1,0} \\ s_{2,0} \\ s_{3,0} \end{pmatrix}, \quad v_1 = \begin{pmatrix} s_{0,1} \\ s_{1,1} \\ s_{2,1} \\ s_{3,1} \end{pmatrix}, \quad v_2 = \begin{pmatrix} s_{0,2} \\ s_{1,2} \\ s_{2,2} \\ s_{3,2} \end{pmatrix}, \quad v_3 = \begin{pmatrix} s_{0,3} \\ s_{1,3} \\ s_{2,3} \\ s_{3,3} \end{pmatrix}. \quad (3.8)$$

300 Thus, the column index c of s becomes the index for v , and the row index r of s becomes the
 301 index for the four bytes in each word.

302 Given a one-dimensional array u of words, $u[i]$ denotes the word that is indexed by i , and the
 303 sequence of four words $u[i], u[i+1], u[i+2], u[i+3]$ is denoted by $u[i..i+3]$.

4. Mathematical Preliminaries

For some transformations of the AES algorithms specified in Sec. 5, each byte in the state array is interpreted as one of the 256 elements of a finite field, also known as a Galois Field, denoted by $\text{GF}(2^8)$.¹

In order to define addition and multiplication in $\text{GF}(2^8)$, each byte $\{b_7 b_6 b_5 b_4 b_3 b_2 b_1 b_0\}$ is interpreted as a polynomial, denoted by $b(x)$, as follows:

$$b(x) = b_7x^7 + b_6x^6 + b_5x^5 + b_4x^4 + b_3x^3 + b_2x^2 + b_1x + b_0. \quad (4.1)$$

For example, $\{01100011\}$ is represented by the polynomial $x^6 + x^5 + x + 1$.

4.1 Addition in $\text{GF}(2^8)$

In order to add two elements in the finite field $\text{GF}(2^8)$, the coefficients of the polynomials that represent the elements are added modulo 2, i.e., with the exclusive-OR operation (denoted by \oplus), so that $1 \oplus 1 = 0$, $1 \oplus 0 = 1$, and $0 \oplus 0 = 0$.

Equivalently, two bytes can be added by applying the exclusive-OR operation to each pair of corresponding bits in the bytes. Thus, the sum of $\{a_7 a_6 a_5 a_4 a_3 a_2 a_1 a_0\}$ and $\{b_7 b_6 b_5 b_4 b_3 b_2 b_1 b_0\}$ is $\{a_7 \oplus b_7 a_6 \oplus b_6 a_5 \oplus b_5 a_4 \oplus b_4 a_3 \oplus b_3 a_2 \oplus b_2 a_1 \oplus b_1 a_0 \oplus b_0\}$. (In Section 5.1.4, this definition is extended to words.)

For example, the following three representations of addition are equivalent:

$$\begin{aligned} (x^6 + x^4 + x^2 + x + 1) + (x^7 + x + 1) &= x^7 + x^6 + x^4 + x^2 && \text{(polynomial);} \\ \{01010111\} \oplus \{10000011\} &= \{11010100\} && \text{(binary);} \\ \{57\} \oplus \{83\} &= \{d4\} && \text{(hexadecimal).} \end{aligned} \quad (4.2)$$

Because the coefficients of the polynomials are reduced modulo 2, the coefficient 1 is equivalent to the coefficient -1 , so addition is equivalent to subtraction. For example, $x^4 + x^2$ represents the same finite field element as $x^4 - x^2$, $-x^4 + x^2$, and $-x^4 - x^2$. Similarly, the sum of any element with itself is the zero element.

4.2 Multiplication in $\text{GF}(2^8)$

The symbol \bullet denotes multiplication in $\text{GF}(2^8)$. Conceptually, this multiplication is defined on two bytes in two steps: 1) the two polynomials that represent the bytes are multiplied as polynomials, and 2) the resulting polynomial is reduced modulo the following fixed polynomial:

$$m(x) = x^8 + x^4 + x^3 + x + 1. \quad (4.3)$$

Within both steps, the individual coefficients of the polynomials are reduced modulo 2.

¹Information about the properties of finite fields can be found in textbooks such as Michael Artin's *Algebra* [4].

329 Thus, if $b(x)$ and $c(x)$ represent bytes b and c , then $b \bullet c$ is represented by the following modular
 330 reduction of their product as polynomials:

$$b(x)c(x) \pmod{m(x)}. \tag{4.4}$$

331 The modular reduction by $m(x)$ may be applied to intermediate steps in the calculation of $b(x)c(x)$;
 332 consequently, it is useful to consider the special case that $c(x) = x$, i.e., $c = \{02\}$. In particular,
 333 the product $b \bullet \{02\}$ can be expressed as a function of b , denoted by $\text{XTIMES}(b)$, as follows:

$$\text{XTIMES}(b) = \begin{cases} \{b_6 b_5 b_4 b_3 b_2 b_1 b_0 0\} & \text{if } b_7 = 0 \\ \{b_6 b_5 b_4 b_3 b_2 b_1 b_0 0\} \oplus \{0 0 0 1 1 0 1 1\} & \text{if } b_7 = 1. \end{cases} \tag{4.5}$$

334 Multiplication by higher powers of x (such as $\{04\}$, $\{08\}$, and $\{10\}$) can be implemented by the
 335 repeated application of $\text{XTIMES}()$. For example, let $b = \{57\}$:

$$\begin{aligned} \{57\} \bullet \{01\} &= \{57\} \\ \{57\} \bullet \{02\} &= \text{XTIMES}(\{57\}) = \{\text{ae}\} \\ \{57\} \bullet \{04\} &= \text{XTIMES}(\{\text{ae}\}) = \{47\} \\ \{57\} \bullet \{08\} &= \text{XTIMES}(\{47\}) = \{8\text{e}\} \\ \{57\} \bullet \{10\} &= \text{XTIMES}(\{8\text{e}\}) = \{07\} \\ \{57\} \bullet \{20\} &= \text{XTIMES}(\{07\}) = \{0\text{e}\} \\ \{57\} \bullet \{40\} &= \text{XTIMES}(\{0\text{e}\}) = \{1\text{c}\} \\ \{57\} \bullet \{80\} &= \text{XTIMES}(\{1\text{c}\}) = \{38\}. \end{aligned} \tag{4.6}$$

These products facilitate the computation of any multiple of $\{57\}$. For example, because $\{13\} = \{10\} \oplus \{02\} \oplus \{01\}$, it follows that

$$\begin{aligned} \{57\} \bullet \{13\} &= \{57\} \bullet (\{01\} \oplus \{02\} \oplus \{10\}) \\ &= \{57\} \oplus \{\text{ae}\} \oplus \{07\} \\ &= \{\text{fe}\}. \end{aligned} \tag{4.7}$$

336 4.3 Multiplication of Words by a Fixed Matrix

337 Two transformations — $\text{MIXCOLUMNS}()$ and $\text{INVMIXCOLUMNS}()$ — in the algorithms for the
 338 AES block ciphers can be expressed in terms of matrix multiplication. In particular, a distinct
 339 fixed matrix is specified for each transformation. For both matrices, each of the sixteen entries of
 340 the matrix is a byte of a single specified word, denoted here by $[a_0, a_1, a_2, a_3]$.

341 Given an input word $[b_0, b_1, b_2, b_3]$ to the transformation, the output word $[d_0, d_1, d_2, d_3]$ is
 342 determined by finite field arithmetic as follows:

$$\begin{aligned}
 d_0 &= (a_0 \bullet b_0) \oplus (a_3 \bullet b_1) \oplus (a_2 \bullet b_2) \oplus (a_1 \bullet b_3) \\
 d_1 &= (a_1 \bullet b_0) \oplus (a_0 \bullet b_1) \oplus (a_3 \bullet b_2) \oplus (a_2 \bullet b_3) \\
 d_2 &= (a_2 \bullet b_0) \oplus (a_1 \bullet b_1) \oplus (a_0 \bullet b_2) \oplus (a_3 \bullet b_3) \\
 d_3 &= (a_3 \bullet b_0) \oplus (a_2 \bullet b_1) \oplus (a_1 \bullet b_2) \oplus (a_0 \bullet b_3).
 \end{aligned}
 \tag{4.8}$$

343 The matrix form of Eq. (4.8) is

$$\begin{bmatrix} d_0 \\ d_1 \\ d_2 \\ d_3 \end{bmatrix} = \begin{bmatrix} a_0 & a_3 & a_2 & a_1 \\ a_1 & a_0 & a_3 & a_2 \\ a_2 & a_1 & a_0 & a_3 \\ a_3 & a_2 & a_1 & a_0 \end{bmatrix} \begin{bmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \end{bmatrix}.
 \tag{4.9}$$

344 4.4 Multiplicative Inverses in $\text{GF}(2^8)$

345 For a byte $b \neq \{00\}$, its multiplicative inverse is the unique byte, denoted by b^{-1} , such that

$$b \bullet b^{-1} = \{01\}. \tag{4.10}$$

346 The definition of the SUBBYTES() transformation in the specifications of the AES block cipher
347 involves multiplicative inverses in $\text{GF}(2^8)$; they can be calculated as follows:

$$b^{-1} = b^{254}. \tag{4.11}$$

348 Alternatively, one can apply the extended Euclidean algorithm [5] to $m(x)$ and $b(x)$ (i.e., the
349 polynomial that represents b to find polynomials $a(x)$ and $c(x)$ such that

$$b(x)a(x) + m(x)c(x) = 1. \tag{4.12}$$

350 It follows that $a(x)$ is the polynomial that represents b^{-1} .

5. Algorithm Specifications

The general function for executing AES-128, AES-192, or AES-256 is denoted by CIPHER(); its inverse is denoted by INVCIPHER().²

The core of the algorithms for CIPHER() and INVCIPHER() is a sequence of fixed transformations of the state, called a *round*. Each round requires an additional input called the *round key*; the round key is a block that is usually represented as a sequence of four words, i.e., 16 bytes.

An expansion routine, denoted by KEYEXPANSION(), takes the block cipher key as input and generates the round keys as output. In particular, the input to KEYEXPANSION() is represented as an array of words, denoted by *key*, and the output is an expanded array of words, denoted by *w*, called the *key schedule*.

The block ciphers AES-128, AES-192, and AES-256 differ in three respects: 1) the length of the key; 2) the number of rounds, which determines the size of the required key schedule; and 3) the specification of the recursion within KEYEXPANSION(). For each algorithm, the number of rounds is denoted by *Nr*, and the number of words of the key is denoted by *Nk*. (The number of words in the state is denoted by *Nb* for Rijndael in general; in this Standard, *Nb* = 4.) The specific values of *Nk*, *Nb*, and *Nr* are given in Table 3; no other configurations of Rijndael conform to this Standard.

For implementation issues relating to the key length, block size, and number of rounds, see Section 6.3.

Table 3. Key-Block-Round Combinations.

	Key length		Block size		Number of rounds
	<i>Nk</i>	(in bits)	<i>Nb</i>	(in bits)	<i>Nr</i>
AES-128	4	128	4	128	10
AES-192	6	192	4	128	12
AES-256	8	256	4	128	14

The three inputs to CIPHER() are: 1) the data input *in*, which is a block represented as a linear array of 16 bytes; 2) the number of rounds *Nr* for the instance; and 3) the round keys. Thus,

$$\begin{aligned}
 \text{AES-128}(in, key) &= \text{CIPHER}(in, 10, \text{KEYEXPANSION}(key)) \\
 \text{AES-192}(in, key) &= \text{CIPHER}(in, 12, \text{KEYEXPANSION}(key)) \\
 \text{AES-256}(in, key) &= \text{CIPHER}(in, 14, \text{KEYEXPANSION}(key)).
 \end{aligned}
 \tag{5.1}$$

The inverse permutations are defined by replacing CIPHER() with INVCIPHER() in Eq. 5.1.

²Informally, these functions are sometimes called “encryption” and “decryption,” but neutral terminology is appropriate because there are other applications of block ciphers besides encryption.

371 The specifications of CIPHER(), KEYEXPANSION(), and INVCIPHER() are given in Sections 5.1,
372 5.2, and 5.3, respectively.

373 5.1 CIPHER()

374 The rounds in the specification of CIPHER() are composed of the following four byte-oriented
375 transformations on the state:

- 376 • SUBBYTES() applies a substitution table (S-box) to each byte,
- 377 • SHIFTRROWS() shifts rows of the state array by different offsets,
- 378 • MIXCOLUMNS() mixes the data within each column of the state array, and
- 379 • ADDROUNDKEY() combines a round key with the state.

380 The four transformations are specified in Sections 5.1.1–5.1.4. In those specifications, the
381 transformed bit, byte, or block is denoted by appending the symbol ' as a superscript on the
382 original variable, i.e., by b'_i , b' , $s'_{i,j}$, or s' .

383 The round keys for ADDROUNDKEY() are generated by KEYEXPANSION(), which is specified in
384 Section 5.2. In particular, the key schedule is represented as an array w of $4 * (Nr + 1)$ words.

385 CIPHER() is specified in the pseudocode in Alg. 1.

Algorithm 1 Pseudocode for CIPHER()

```

1: procedure CIPHER(in, w, Nr)
2:   state ← in                                     ▷ See Sec. 3.4
3:   state ← ADDROUNDKEY(state, w[0..3])           ▷ See Sec. 5.1.4
4:   for round from 1 to Nr − 1 do
5:     state ← SUBBYTES(state)                     ▷ See Sec. 5.1.1
6:     state ← SHIFTRROWS(state)                   ▷ See Sec. 5.1.2
386 7:     state ← MIXCOLUMNS(state)                 ▷ See Sec. 5.1.3
8:     state ← ADDROUNDKEY(state, w[4 * round..4 * round + 3])
9:   end for
10:  state ← SUBBYTES(state)
11:  state ← SHIFTRROWS(state)
12:  state ← ADDROUNDKEY(state, w[4 * Nr..4 * Nr + 3])
13:  return state                                   ▷ See Sec. 3.4
14: end procedure

```

387 The first step (Line 2) is to copy the input into the state array using the conventions from Sec. 3.4
388 After an initial round key addition (Line 3), the state array is transformed by Nr applications of
389 the round function (Lines 4–12); the final round (Lines 10–12) differs in that the MIXCOLUMNS()
390 transformation is omitted. The final state is then returned as the output (Line 13) as described in
391 Section 3.4.

392 **5.1.1 SUBBYTES()**

393 SUBBYTES() is an invertible, non-linear transformation of the state in which a substitution table,
 394 called an S-box, is applied independently to each byte in the state. The AES S-box is denoted by
 395 SBOX().

396 Let b denote a byte that is input byte to SBOX(), and let c denote the constant byte $\{01100011\}$.
 397 The output byte $b' = \text{SBOX}(b)$ is constructed by composing the following two transformations:

1. Define an intermediate value \tilde{b} , as follows, where b^{-1} is the multiplicative inverse of b , as described in Section 4.4:

$$\tilde{b} = \begin{cases} \{00\} & \text{if } b = \{00\} \\ b^{-1} & \text{if } b \neq \{00\}. \end{cases} \tag{5.2}$$

2. Apply the following affine transformation of the bits of \tilde{b} to produce the bits of b' :

$$b'_i = \tilde{b}_i \oplus \tilde{b}_{(i+4) \bmod 8} \oplus \tilde{b}_{(i+5) \bmod 8} \oplus \tilde{b}_{(i+6) \bmod 8} \oplus \tilde{b}_{(i+7) \bmod 8} \oplus c_i. \tag{5.3}$$

399 The matrix form of Eq. (5.3) is given by Eq. (5.4) below:

$$\begin{bmatrix} b'_0 \\ b'_1 \\ b'_2 \\ b'_3 \\ b'_4 \\ b'_5 \\ b'_6 \\ b'_7 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} \tilde{b}_0 \\ \tilde{b}_1 \\ \tilde{b}_2 \\ \tilde{b}_3 \\ \tilde{b}_4 \\ \tilde{b}_5 \\ \tilde{b}_6 \\ \tilde{b}_7 \end{bmatrix} + \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ 1 \\ 1 \\ 0 \end{bmatrix}. \tag{5.4}$$

400 Figure 2 illustrates how SUBBYTES() transforms the state.

Figure 2. Illustration of SUBBYTES().

401 The AES S-box is presented in hexadecimal form in Table 4. For example, if $s_{r,c} = \{53\}$, then

Table 4. SBOX(): substitution values for the byte x_y (in hexadecimal format).

		y															
		0	1	2	3	4	5	6	7	8	9	a	b	c	d	e	f
x	0	63	7c	77	7b	f2	6b	6f	c5	30	01	67	2b	fe	d7	ab	76
	1	ca	82	c9	7d	fa	59	47	f0	ad	d4	a2	af	9c	a4	72	c0
	2	b7	fd	93	26	36	3f	f7	cc	34	a5	e5	f1	71	d8	31	15
	3	04	c7	23	c3	18	96	05	9a	07	12	80	e2	eb	27	b2	75
	4	09	83	2c	1a	1b	6e	5a	a0	52	3b	d6	b3	29	e3	2f	84
	5	53	d1	00	ed	20	fc	b1	5b	6a	cb	be	39	4a	4c	58	cf
	6	d0	ef	aa	fb	43	4d	33	85	45	f9	02	7f	50	3c	9f	a8
	7	51	a3	40	8f	92	9d	38	f5	bc	b6	da	21	10	ff	f3	d2
	8	cd	0c	13	ec	5f	97	44	17	c4	a7	7e	3d	64	5d	19	73
	9	60	81	4f	dc	22	2a	90	88	46	ee	b8	14	de	5e	0b	db
	a	e0	32	3a	0a	49	06	24	5c	c2	d3	ac	62	91	95	e4	79
	b	e7	c8	37	6d	8d	d5	4e	a9	6c	56	f4	ea	65	7a	ae	08
	c	ba	78	25	2e	1c	a6	b4	c6	e8	dd	74	1f	4b	bd	8b	8a
	d	70	3e	b5	66	48	03	f6	0e	61	35	57	b9	86	c1	1d	9e
	e	e1	f8	98	11	69	d9	8e	94	9b	1e	87	e9	ce	55	28	df
	f	8c	a1	89	0d	bf	e6	42	68	41	99	2d	0f	b0	54	bb	16

402 the substitution value would be determined by the intersection of the row with index ‘5’ and the
 403 column with index ‘3’ in Table 4, i.e., $s'_{r,c} = \{ed\}$.

404 **5.1.2 SHIFTRows()**

405 SHIFTRows() is a transformation of the state in which the bytes in the last three rows of the state
 406 are cyclically shifted. The number of positions by which the bytes are shifted depends on the row
 407 index r , as follows:

$$s'_{r,c} = s_{r,(c+r) \bmod 4} \quad \text{for } 0 \leq r < 4 \text{ and } 0 \leq c < 4. \tag{5.5}$$

408 SHIFTRows() is illustrated in Figure 3. In that representation of the state, the effect is to move
 409 each byte by r positions to the left in the row, cycling the left-most $r - 1$ bytes around to the right
 410 end of the row; the first row, where $r = 0$, is unchanged.

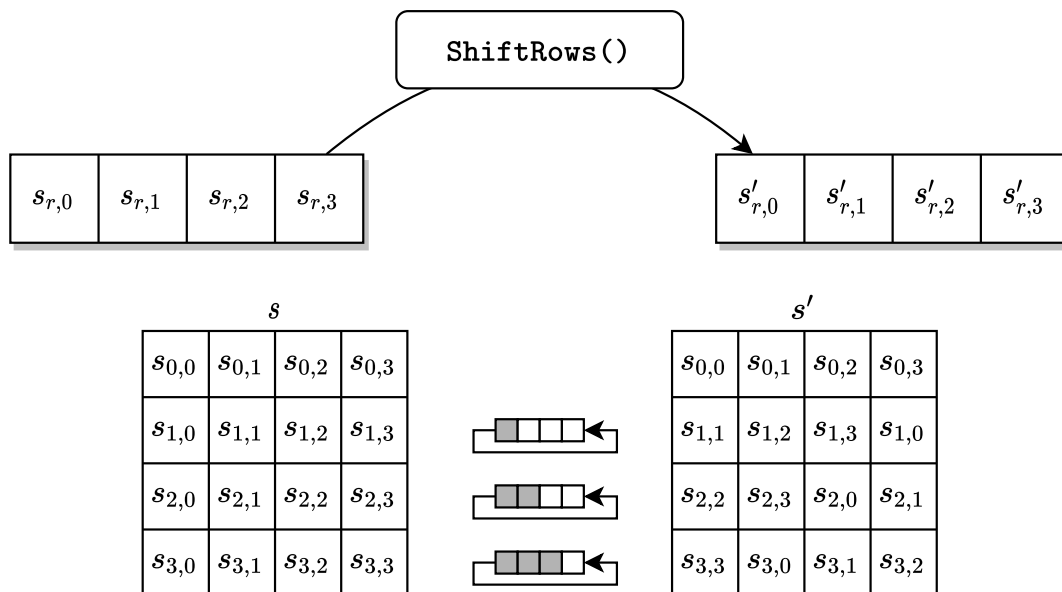

Figure 3. Illustration of SHIFTRows().

411 **5.1.3 MIXCOLUMNS()**

412 MIXCOLUMNS() is a transformation of the state that multiplies each of the four columns of the
 413 state by a single fixed matrix, as described in Section 4.3, with its entries taken from the following
 414 word:

$$[a_0, a_1, a_2, a_3] = [\{02\}, \{01\}, \{01\}, \{03\}]. \tag{5.6}$$

Thus,

$$\begin{bmatrix} s'_{0,c} \\ s'_{1,c} \\ s'_{2,c} \\ s'_{3,c} \end{bmatrix} = \begin{bmatrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{bmatrix} \begin{bmatrix} s_{0,c} \\ s_{1,c} \\ s_{2,c} \\ s_{3,c} \end{bmatrix} \quad \text{for } 0 \leq c < 4, \tag{5.7}$$

so that the individual output bytes are defined as follows:

$$\begin{aligned} s'_{0,c} &= (\{02\} \bullet s_{0,c}) \oplus (\{03\} \bullet s_{1,c}) \oplus s_{2,c} \oplus s_{3,c} \\ s'_{1,c} &= s_{0,c} \oplus (\{02\} \bullet s_{1,c}) \oplus (\{03\} \bullet s_{2,c}) \oplus s_{3,c} \\ s'_{2,c} &= s_{0,c} \oplus s_{1,c} \oplus (\{02\} \bullet s_{2,c}) \oplus (\{03\} \bullet s_{3,c}) \\ s'_{3,c} &= (\{03\} \bullet s_{0,c}) \oplus s_{1,c} \oplus s_{2,c} \oplus (\{02\} \bullet s_{3,c}). \end{aligned} \tag{5.8}$$

415 Figure 4 illustrates MIXCOLUMNS().

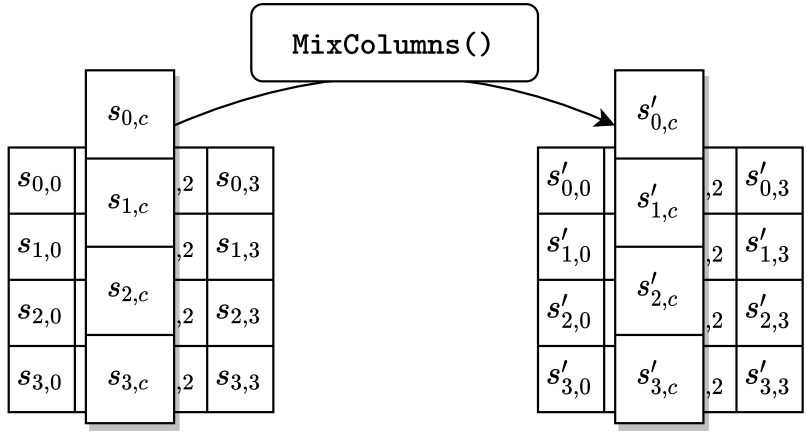

Figure 4. Illustration of MIXCOLUMNS().

5.1.4 ADDROUNDKEY()

ADDRoundKey() is a transformation of the state in which a round key is combined with the state by applying the bitwise XOR operation. In particular, each round key consists of four words from the key schedule (described in Section 5.2), each of which is combined with a column of the state as follows:

$$[s'_{0,c}, s'_{1,c}, s'_{2,c}, s'_{3,c}] = [s_{0,c}, s_{1,c}, s_{2,c}, s_{3,c}] \oplus [w_{(4*round+c)}] \quad \text{for } 0 \leq c < 4 \quad (5.9)$$

where *round* is a value in the range $0 \leq \text{round} \leq Nr$, and $w[i]$ is the array of key schedule words described in Section 5.2. In the specification of CIPHER(), ADDRoundKey() is invoked $Nr + 1$ times, once when $\text{round} = 0$, prior to the first application of the round function (see Alg. 1), and once within each of the Nr rounds, i.e., when $1 \leq \text{round} \leq Nr$.

The action of this transformation is illustrated in Fig. 5, where $l = 4 * \text{round}$. The byte address within words of the key schedule was described in Sec. 3.1.

Figure 5. Illustration of ADDRoundKey().

427 **5.2 KEYEXPANSION()**

428 KEYEXPANSION() is a routine that is applied to the key to generate $4 * (Nr + 1)$ words, i.e.,
 429 four words for each of the $Nr + 1$ applications of ADDROUNDKEY() within the specification of
 430 CIPHER(), as described in Section 5.1.4. The output of the routine consists of a linear array of
 431 words, denoted by $w[i]$, with i in the range $0 \leq i < 4 * (Nr + 1)$.

432 KEYEXPANSION() invokes ten fixed words denoted by $Rcon[j]$ for $1 \leq j \leq 10$. These ten words
 433 are called the *round constants*. For AES-128, a distinct round constant is called in the generation
 434 of each of the ten round keys. For AES-192 and AES-256, the key expansion routine calls
 435 the first eight and six of these same constants, respectively. The values of $Rcon[j]$ are given in
 436 hexadecimal notation in Table 5:

Table 5. Round constants.

j	$Rcon[j]$	j	$Rcon[j]$
1	[01, 00, 00, 00]	6	[20, 00, 00, 00]
2	[02, 00, 00, 00]	7	[40, 00, 00, 00]
3	[04, 00, 00, 00]	8	[80, 00, 00, 00]
4	[08, 00, 00, 00]	9	[1b, 00, 00, 00]
5	[10, 00, 00, 00]	10	[36, 00, 00, 00]

437 The value of the left-most byte of $Rcon[j]$ in polynomial form is x^{j-1} . Note that for $j > 0$, these
 438 bytes may be generated by successively applying XTIMES() to the byte represented by x^{j-1} ; see
 439 Eq. 4.5.

440 Two transformations on words are called within KEYEXPANSION(): ROTWORD() and SUB-
 441 WORD(). Given an input word, i.e., a sequence $[a_0, a_1, a_2, a_3]$ of four bytes,

$$\text{ROTWORD}([a_0, a_1, a_2, a_3]) = [a_1, a_2, a_3, a_0], \tag{5.10}$$

and

$$\text{SUBWORD}([a_0, \dots, a_3]) = [\text{SBOX}(a_0), \text{SBOX}(a_1), \text{SBOX}(a_2), \text{SBOX}(a_3)]. \tag{5.11}$$

442 The expansion of the key proceeds according to the pseudocode in Alg. 2. The first Nk words of
 443 the expanded key are the key itself. Every subsequent word $w[i]$ is generated recursively from the
 444 preceding word, $w[i - 1]$, and the word Nk positions earlier, $w[i - Nk]$, as follows:

- 445 • If i is a multiple of Nk , then $w[i] = w[i - Nk] \oplus \text{SUBWORD}(\text{ROTWORD}(w[i - 1])) \oplus$
 446 $Rcon[i/Nk]$.
- 447 • For AES-256, if $i + 4$ is a multiple of 8, then $w[i] = w[i - Nk] \oplus \text{SUBWORD}(w[i - 1])$.
- 448 • For all other cases, $w[i] = w[i - Nk] \oplus w[i - 1]$.

Algorithm 2 Pseudocode for KEYEXPANSION()

```

1: procedure KEYEXPANSION(key)
2:    $i \leftarrow 0$ 
3:   while  $i \leq Nk - 1$  do
4:      $w[i] \leftarrow key[4 * i..4 * i + 3]$ 
5:      $i \leftarrow i + 1$ 
6:   end while
7:   while  $i \leq 4 * Nr + 3$  do
8:      $temp \leftarrow w[i - 1]$ 
9:     if  $i \bmod Nk = 0$  then
10:       $temp \leftarrow \text{SUBWORD}(\text{ROTWORD}(temp)) \oplus Rcon[i/Nk]$ 
11:     else if  $Nk > 6$  and  $i \bmod Nk = 4$  then
12:       $temp \leftarrow \text{SUBWORD}(temp)$ 
13:     end if
14:      $w[i] \leftarrow w[i - Nk] \oplus temp$ 
15:      $i \leftarrow i + 1$ 
16:   end while
17:   return  $w$ 
18: end procedure

```

449

450 Figures 6, 7, and 8 illustrate KEYEXPANSION() for AES-128, AES-192, and AES-256.

451 5.3 INVCIPHER()

452 To implement INVCIPHER(), the transformations in the specification of CIPHER() (Section 5.1)
 453 are inverted and executed in reverse order. The inverted transformations of the state—denoted
 454 by INVSHIFTROWS(), INVSUBBYTES(), INVMIXCOLUMNS(), and ADDROUNDKEY()—are
 455 described in Sections 5.3.1–5.3.4.

456 INVCIPHER() is described in the pseudocode in Alg. 3, where the array w denotes the key
 457 schedule, as described in Section 5.2.

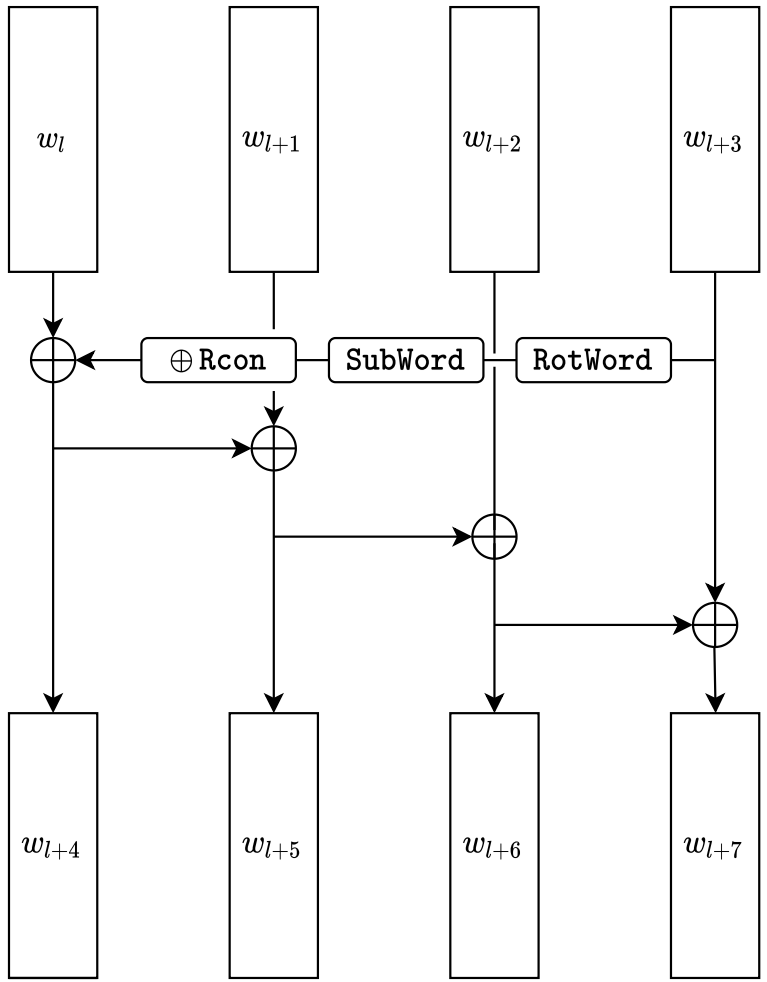

Figure 6. KEYEXPANSION() of AES-128 to generate the words $w[i]$ for $4 \leq i < 44$.

Figure 7. KEYEXPANSION() of AES-192 to generate the words $w[i]$ for $6 \leq i < 52$.

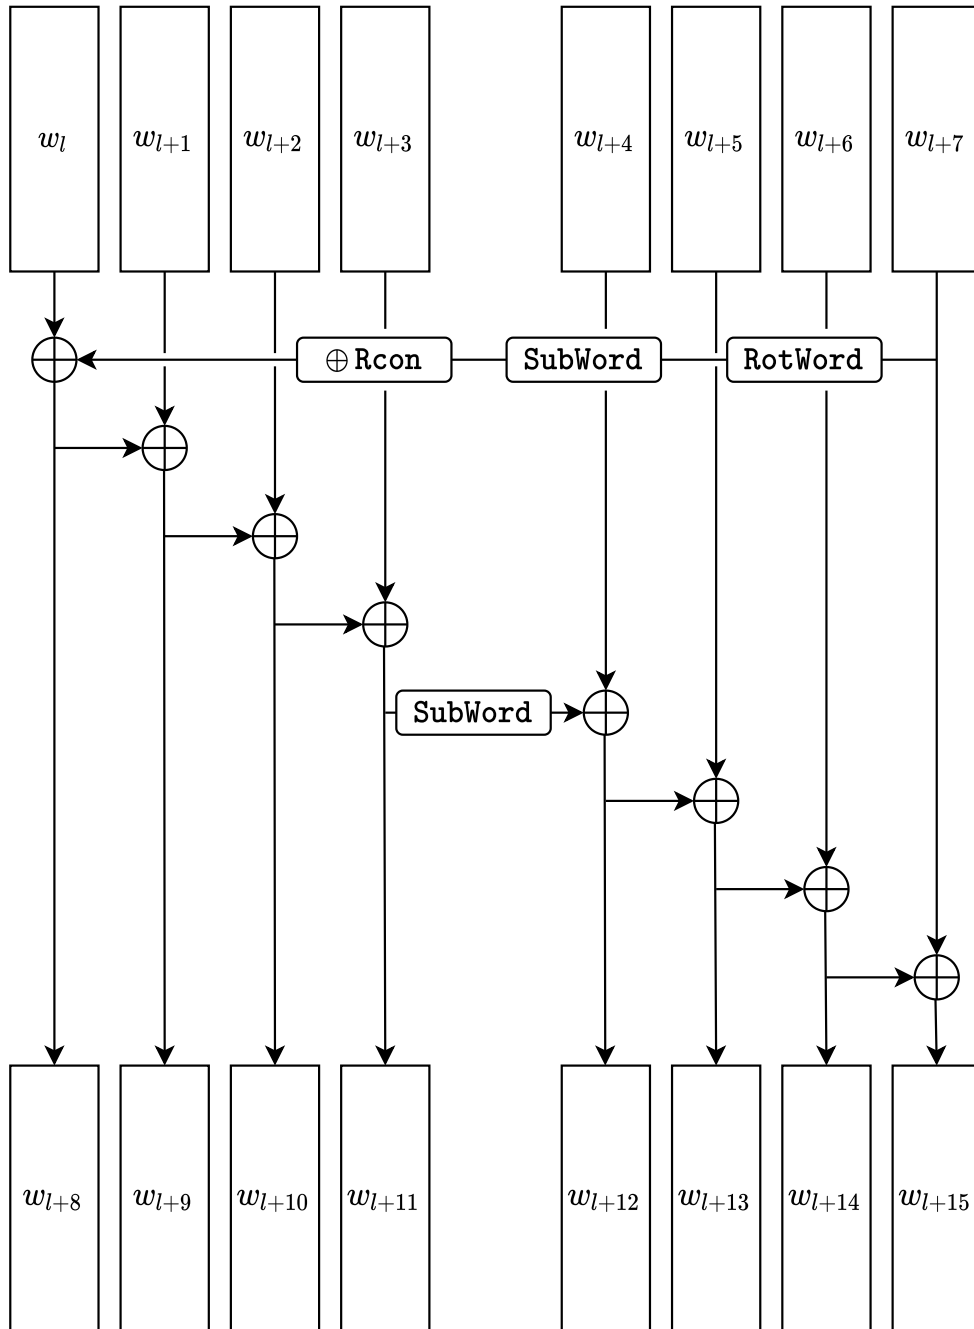

Figure 8. KEYEXPANSION() of AES-256 to generate the words $w[i]$ for $8 \leq i < 60$.

Algorithm 3 Pseudocode for INVCIPHER()

```

1: procedure INVCIPHER(in, w, Nr)
2:   state ← in                                     ▷ See Sec. 3.4
3:   state ← ADDROUNDKEY(state, w[4 * Nr..4 * Nr + 3])  ▷ See Sec. 5.1.4
4:   for round from Nr − 1 downto 1 do
5:     state ← INVSHIFTRROWS(state)                 ▷ See Sec. 5.3.1
6:     state ← INVSUBBYTES(state)                   ▷ See Sec. 5.3.2
7:     state ← ADDROUNDKEY(state, w[4 * round..4 * round + 3])
8:     state ← INVMIXCOLUMNS(state)                ▷ See Sec. 5.3.3
9:   end for
10:  state ← INVSHIFTRROWS(state)
11:  state ← INVSUBBYTES(state)
12:  state ← ADDROUNDKEY(state, w[0..3])
13:  return state
14: end procedure

```

5.3.1 INVSHIFTRROWS()

INVSHIFTRROWS() is the inverse of the SHIFTRROWS(): the bytes in the last three rows of the state are cyclically shifted as follows:

$$s'_{r,c} = s_{r,(c-r) \bmod 4} \quad \text{for } 0 \leq r < 4 \text{ and } 0 \leq c < 4. \tag{5.12}$$

INVSHIFTRROWS() is illustrated in Figure 9. In that representation of the state, the effect is to move each byte by *r* positions to the right in the row, cycling the right-most *r* − 1 bytes around to the left end of the row; the first row, where *r* = 0, is unchanged.

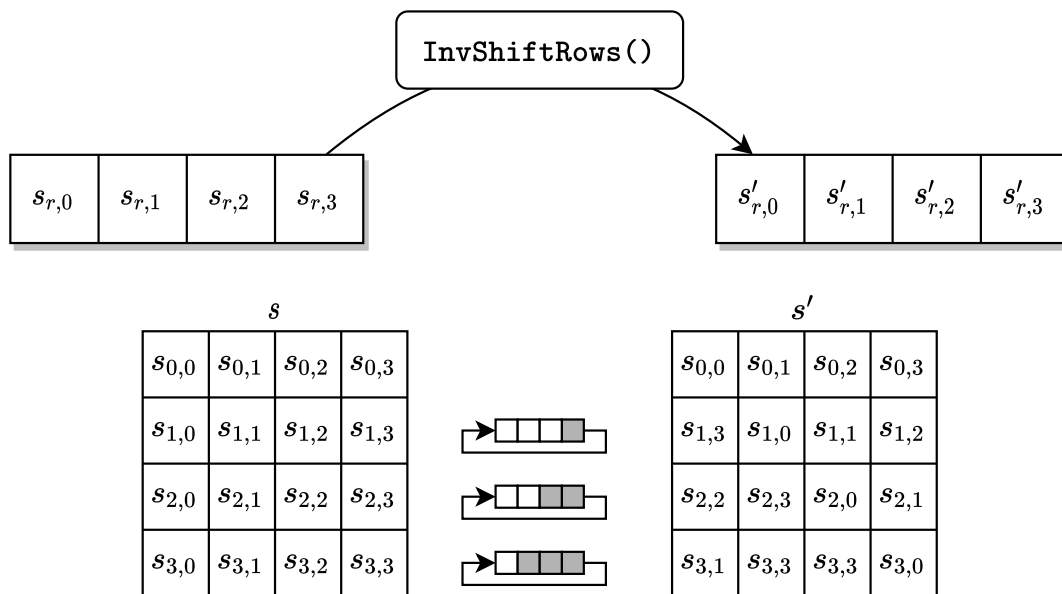

Figure 9. Illustration of INVSHIFTRROWS().

465 **5.3.2 INVSUBBYTES()**

466 INVSUBBYTES() is the inverse of SUBBYTES(), in which the inverse of SBOX(), denoted by
 467 INVSBOX(), is applied to each byte of the state. INVSBOX() is derived from Table 4 by switching
 468 the roles of inputs and outputs, as presented in Table 6:

Table 6. INVSBOX(): substitution values for the byte x_y (in hexadecimal format).

		y															
		0	1	2	3	4	5	6	7	8	9	a	b	c	d	e	f

	9	96	ac	74	22	e7	ad	35	85	e2	f9	37	e8	1c	75	df	6e
	a	47	f1	1a	71	1d	29	c5	89	6f	b7	62	0e	aa	18	be	1b
	b	fc	56	3e	4b	c6	d2	79	20	9a	db	c0	fe	78	cd	5a	f4
	c	1f	dd	a8	33	88	07	c7	31	b1	12	10	59	27	80	ec	5f
	d	60	51	7f	a9	19	b5	4a	0d	2d	e5	7a	9f	93	c9	9c	ef
	e	a0	e0	3b	4d	ae	2a	f5	b0	c8	eb	bb	3c	83	53	99	61
	f	17	2b	04	7e	ba	77	d6	26	e1	69	14	63	55	21	0c	7d

469 **5.3.3 INVMIXCOLUMNS()**

470 INVMIXCOLUMNS() is the inverse of MIXCOLUMNS(); it multiplies each of the four columns
 471 of the state by a single fixed matrix, as described in Section 4.3, with its entries taken from the
 472 following word:

$$[a_0, a_1, a_2, a_3] = [\{0e\}, \{09\}, \{0d\}, \{0b\}]. \tag{5.13}$$

473 Thus,

$$\begin{bmatrix} s'_{0,c} \\ s'_{1,c} \\ s'_{2,c} \\ s'_{3,c} \end{bmatrix} = \begin{bmatrix} 0e & 0b & 0d & 09 \\ 09 & 0e & 0b & 0d \\ 0d & 09 & 0e & 0b \\ 0b & 0d & 09 & 0e \end{bmatrix} \begin{bmatrix} s_{0,c} \\ s_{1,c} \\ s_{2,c} \\ s_{3,c} \end{bmatrix} \quad \text{for } 0 \leq c < 4. \tag{5.14}$$

As a result of this matrix multiplication, the four bytes in a column are replaced by the following:

$$\begin{aligned} s'_{0,c} &= (\{0e\} \cdot s_{0,c}) \oplus (\{0b\} \cdot s_{1,c}) \oplus (\{0d\} \cdot s_{2,c}) \oplus (\{09\} \cdot s_{3,c}) \\ s'_{1,c} &= (\{09\} \cdot s_{0,c}) \oplus (\{0e\} \cdot s_{1,c}) \oplus (\{0b\} \cdot s_{2,c}) \oplus (\{0d\} \cdot s_{3,c}) \\ s'_{2,c} &= (\{0d\} \cdot s_{0,c}) \oplus (\{09\} \cdot s_{1,c}) \oplus (\{0e\} \cdot s_{2,c}) \oplus (\{0b\} \cdot s_{3,c}) \\ s'_{3,c} &= (\{0b\} \cdot s_{0,c}) \oplus (\{0d\} \cdot s_{1,c}) \oplus (\{09\} \cdot s_{2,c}) \oplus (\{0e\} \cdot s_{3,c}). \end{aligned} \tag{5.15}$$

474 **5.3.4 Inverse of ADDROUNDKEY()**

475 ADDROUNDKEY(), described in Section 5.1.4, is its own inverse.

476 **5.3.5 EQINVCIPHER()**

477 Several properties of the AES algorithm allow for an alternative specification of the inverse of
 478 CIPHER(), called the *equivalent inverse cipher*, denoted by EQINVCIPHER(). In the specification
 479 of EQINVCIPHER(), the transformations of the round function of the cipher in Alg. 1 are directly
 480 replaced by their inverses in EQINVCIPHER(), i.e., in the same order. The efficiency of this
 481 structure in comparison to the specification of INVCIPHER() in Alg. 3 is explained in the Rijndael
 482 proposal document [2].

483 Pseudocode for the equivalent inverse cipher is given in Alg. 4; it uses a modified key schedule,
 484 denoted by the word array dw . The routine to generate dw is an extension of KEYEXPANSION(),
 485 denoted by KEYEXPANSIONEIC(); its pseudocode is given in Alg. 5.

Algorithm 4 Pseudocode for EQINVCIPHER()

```

1: procedure EQINVCIPHER( $in, dw, Nr$ )
2:    $state \leftarrow in$ 
3:    $state \leftarrow \text{ADDROUNDKEY}(state, dw[4 * Nr..4 * Nr + 3])$ 
4:   for  $round$  from  $Nr - 1$  downto 1 do
5:      $state \leftarrow \text{INVSUBBYTES}(state)$ 
6:      $state \leftarrow \text{INVSHIFTRROWS}(state)$ 
7:      $state \leftarrow \text{INVMIXCOLUMNS}(state)$ 
8:      $state \leftarrow \text{ADDROUNDKEY}(state, dw[4 * round..4 * round + 3])$ 
9:   end for
10:   $state \leftarrow \text{INVSUBBYTES}(state)$ 
11:   $state \leftarrow \text{INVSHIFTRROWS}(state)$ 
12:   $state \leftarrow \text{ADDROUNDKEY}(state, dw[0..3])$ 
13:  return  $state$ 
14: end procedure

```

Algorithm 5 Pseudocode for KEYEXPANSIONEIC()

```

1: procedure KEYEXPANSIONEIC(key)
2:    $i \leftarrow 0$ 
3:   while  $i \leq Nk - 1$  do
4:      $w[i] \leftarrow key[4i..4i + 3]$ 
5:      $dw[i] \leftarrow w[i]$ 
6:      $i \leftarrow i + 1$ 
7:   end while
8:   while  $i \leq 4 * Nr + 3$  do
9:      $temp \leftarrow w[i - 1]$ 
10:    if  $i \bmod Nk = 0$  then
11:       $temp \leftarrow \text{SUBWORD}(\text{ROTWORD}(temp)) \oplus Rcon[i/Nk]$ 
12:    else if  $Nk > 6$  and  $i \bmod Nk = 4$  then
13:       $temp \leftarrow \text{SUBWORD}(temp)$ 
14:    end if
15:     $w[i] \leftarrow w[i - Nk] \oplus temp$ 
16:     $dw[i] \leftarrow w[i]$ 
17:     $i \leftarrow i + 1$ 
18:  end while
19:  for round from 1 to  $Nr - 1$  do
20:     $i \leftarrow 4 * round$ 
21:     $dw[i..i + 3] \leftarrow \text{INVMIXCOLUMNS}(dw[i..i + 3])$   $\triangleright$  Note change of type.
22:  end for
23:  return dw
24: end procedure

```

487

488 The first and last round keys in *dw* are the same as in *w*; the modification of the other round keys
489 is described in Lines 18–21. The comment in Line 21 refers to the input to INVMIXCOLUMNS():
490 the one-dimensional array of words is converted to a two-dimensional array of bytes, as in Fig. 1.

6. Implementation Considerations

6.1 Key Length Requirements

An implementation of the AES algorithm shall support at least one of the three key lengths specified in Sec. 5: 128, 192, or 256 bits (i.e., $Nk = 4, 6,$ or $8,$ respectively). Implementations may optionally support two or three key lengths, which may promote the interoperability of algorithm implementations.

6.2 Keying Restrictions

When a cryptographic key has been generated appropriately (see NIST Special Publication 800-133 Rev. 2 [6] for guidelines), no restriction is imposed when the resulting key is used for the AES algorithm.

6.3 Parameter Extensions

This Standard explicitly defines the allowed values for the key length (Nk), block size (Nb), and number of rounds (Nr) — see Fig. 3. However, future reaffirmations of this Standard could include changes or additions to the allowed values for those parameters. Therefore, implementers may choose to design their AES implementations with future flexibility in mind.

6.4 Implementation Suggestions Regarding Various Platforms

Implementation variations are possible that may, in many cases, offer performance or other advantages. Given the same input key and data (plaintext or ciphertext), any implementation that produces the same output (ciphertext or plaintext) as the algorithm specified in this Standard is an equivalent implementation of the AES algorithm.

The AES proposal document [2] and other resources located on the AES page [7] include suggestions on how to efficiently implement the AES algorithm on a variety of platforms. Suggested implementations are intended to explain the inner workings of the AES algorithm but do not provide protection against various implementation attacks.

A physical implementation may leak key-dependent information through side channels, such as the time taken to perform a computation, or when faults are injected into the computation. When such attacks are non-invasive, they can be effective even when there are mechanisms to detect physical tampering of the device. For example, cache-timing attacks may affect AES implementations on software platforms that use a cache to accelerate the access to data from main memory.

Protecting implementations of the AES algorithm against implementation attacks where applicable should be considered. Such considerations are outside the scope of this document but are taken into account when testing for conformance to the algorithm in this Standard according to the validation program developed by NIST: <https://nist.gov/cmvp>.

525 **6.5 Modes of Operation**

526 Block cipher modes of operation are cryptographic functions that feature a block cipher to provide
527 information services, such as confidentiality and authentication. NIST-recommended modes of
528 operation are specified in the 800-38 series of NIST Special Publications; further information is
529 available at <https://csrc.nist.gov/Projects/block-cipher-techniques/BCM>.

567 Appendix A — Key Expansion Examples

568 This appendix shows the development of the key schedule for each key size. Note that multi-byte
 569 values are presented using the notation described in Sec. 3. The intermediate values produced
 570 during the development of the key schedule (see Sec. 5.2) are given in the following table (all
 571 values are in hexadecimal format, with the exception of the index column (i)).

572 A.1 Expansion of a 128-bit Key

573 This section contains the key expansion of the following key:

574 Key = 2b 7e 15 16 28 ae d2 a6 ab f7 15 88 09 cf 4f 3c

575 for $Nk = 4$, which results in

$$w_0 = 2b7e1516 \quad w_1 = 28aed2a6 \quad w_2 = abf71588 \quad w_3 = 09cf4f3c$$

667 A.3 Expansion of a 256-bit Key

668 This section contains the key expansion of the following key:

Key = 60 3d eb 10 15 ca 71 be 2b 73 ae f0 85 7d 77 81
 1f 35 2c 07 3b 61 08 d7 2d 98 10 a3 09 14 df f4

669 for $Nk = 8$, which results in

$w_0 = 603deb10$ $w_1 = 15ca71be$ $w_2 = 2b73aef0$ $w_3 = 857d7781$
 $w_4 = 1f352c07$ $w_5 = 3b6108d7$ $w_6 = 2d9810a3$ $w_7 = 0914dff4$

670	i (dec)	$temp$	After ROTWORD ()	After SUBWORD ()	$Rcon[i/Nk]$	After XOR with $Rcon$	$w[i - Nk]$	$w[i] =$ $temp \oplus$ $w[i - Nk]$

723 **Appendix B — Cipher Example**

724 The following diagram shows the values in the state array as the cipher progresses for a block
 725 length and a key length of 16 bytes each (i.e., $Nb = 4$ and $Nk = 4$).

Input = 32 43 f6 a8 88 5a 30 8d 31 31 98 a2 e0 37 07 34
 Key = 2b 7e 15 16 28 ae d2 a6 ab f7 15 88 09 cf 4f 3c

726 The Round Key values are taken from the Key Expansion example in Appendix A.1.

752 **Appendix C — Example Vectors**

753 The NIST Computer Security Resource Center provides a web page with “examples with inter-
754 mediate values” for AES [[10](#)].

755 **Appendix D — Change Log (Informative)**

756 The original FIPS 197 (November 26, 2001) was reviewed and updated under the auspices of
757 NIST’s Crypto Publication Review Board [11]. Public comments and the analyses of the security
758 of the AES that are described in NISTIR 8319 [13] were the basis for the decision to maintain the
759 technical specifications of the Standard.

760 The following is a summary of the editorial changes to the original FIPS 197 in the December 19,
761 2022 update, NIST FIPS 197-upd1 (initial public draft):

- 762 1. The formatting of many elements of the publication was improved, and a lot of text was
763 revised for clarity.
- 764 2. The following items were added to the frontmatter: title page, foreword, abstract, and
765 keywords. Officials’ names and affiliations on the title page reflect the original publication.
- 766 3. The announcement sections were updated to reflect current statutes, regulations, standards,
767 guidelines, and validation programs.
- 768 4. Section 1 was revised to 1) add and update references to the AES development effort, and
769 2) explicitly name AES-128, AES-192, and AES-256.
- 770 5. The material in the previous Section 2.2 (Algorithms Parameters, Symbols and Functions)
771 was split into two new sections: 2.2 (List of Functions) and 2.3 (Algorithm Parameters and
772 Symbols).
- 773 6. The terms, functions, and symbols from the specifications are comprehensively included in
774 the lists in Sections 2.1-2.3.
- 775 7. The description of the indexing convention was removed from Section 3.1.
- 776 8. Table 1 was revised, and the text in the previous Section 3.2 on the polynomial interpretation
777 of bytes was revised and moved to Section 4.
- 778 9. A general definition of the indexing of byte sequences was added to Section 3.3 before
779 specializing to the example of a block; also, Table 2 was revised.
- 780 10. The heading for Section 3.5 was changed to focus on word arrays, and notation for them
781 was included in the text. Also, the column words of the state were presented in a vertical
782 format, with an improved description of the indices.
- 783 11. A reference for additional information on finite fields [8] was included in a footnote within
784 Section 4, and the headings for Sections 4.1 and 4.2 were revised to explicitly mention
785 $GF(2^8)$.
- 786 12. Section 4.2 was revised to provide an explicit, general description of finite field multi-
787 plication. The previous Section 4.2.1 was incorporated into the revised Section 4.2: the
788 illustration of finite field multiplication using x_{time} replaced the original example of
789 modular polynomial reduction.
- 790 13. The heading of Section 4.3 was revised to focus on multiplication by a fixed matrix, and the
791 text of the section was simplified by removing the secondary interpretation as polynomial

- 792 reduction. The descriptions of `MIXCOLUMNS()` and `INVMIXCOLUMNS()` in Sections 5.1.3
793 and 5.3.3 were revised accordingly, to refer back to this construction.
- 794 14. The text on multiplicative inverses in $GF(2^8)$ from the previous Section 4.2 was revised
795 and moved to the new Section 4.4.
- 796 15. The discussion of the algorithm specifications in Section 5 was expanded to elaborate
797 on the relationships among its components. Also, a brief, new explanation of Nb as a
798 Rijndael parameter enabled the replacement of Nb with its constant value 4 in the rest of
799 the Standard.
- 800 16. The pseudocode for the cipher, the key expansion routine, and the inverse cipher in Sections
801 5.1, 5.2, and 5.3 was reformatted, and some of the text in these sections was revised for
802 clarity.
- 803 17. The descriptions of `SHIFTRROWS()` in Section 5.1.2 and `INVSHIFTRROWS()` in Section 5.3.2
804 were improved, and a mistake in the latter was corrected.
- 805 18. Illustrations of the three instances of `KEYEXPANSION()` in the new Figs. 6, 7, and 8 were
806 added to Section 5.2. Also, the text in the section was revised, including an explicit display
807 of the round constants in the new Fig. 5.
- 808 19. A separate algorithm for the modified key expansion routine for the equivalent inverse
809 cipher was added to Section 5.3.5 instead of only the supplementary lines. The description
810 of the equivalent inverse cipher was simplified in favor of the citation of an updated
811 reference [3].
- 812 20. Section 6.2 was revised to include a reference to the NIST Special Publication on crypto-
813 graphic key generation [6].
- 814 21. Section 6.4 was revised to expand the discussion of implementation attacks.
- 815 22. The References section is no longer labeled as an appendix. The references were updated
816 to replace withdrawn publications and correct citation information and URLs.
- 817 23. The examples in Appendix C were removed in favor of a reference to the detailed example
818 vectors that are now maintained at [10].
- 819 24. Appendix D was created to summarize the changes in this update to FIPS 197.
